

“Insulin therapy should  
be the treatment of choice for type 2  
diabetes complicated by CHD”

Opposed by Simon Heller  
University of Sheffield

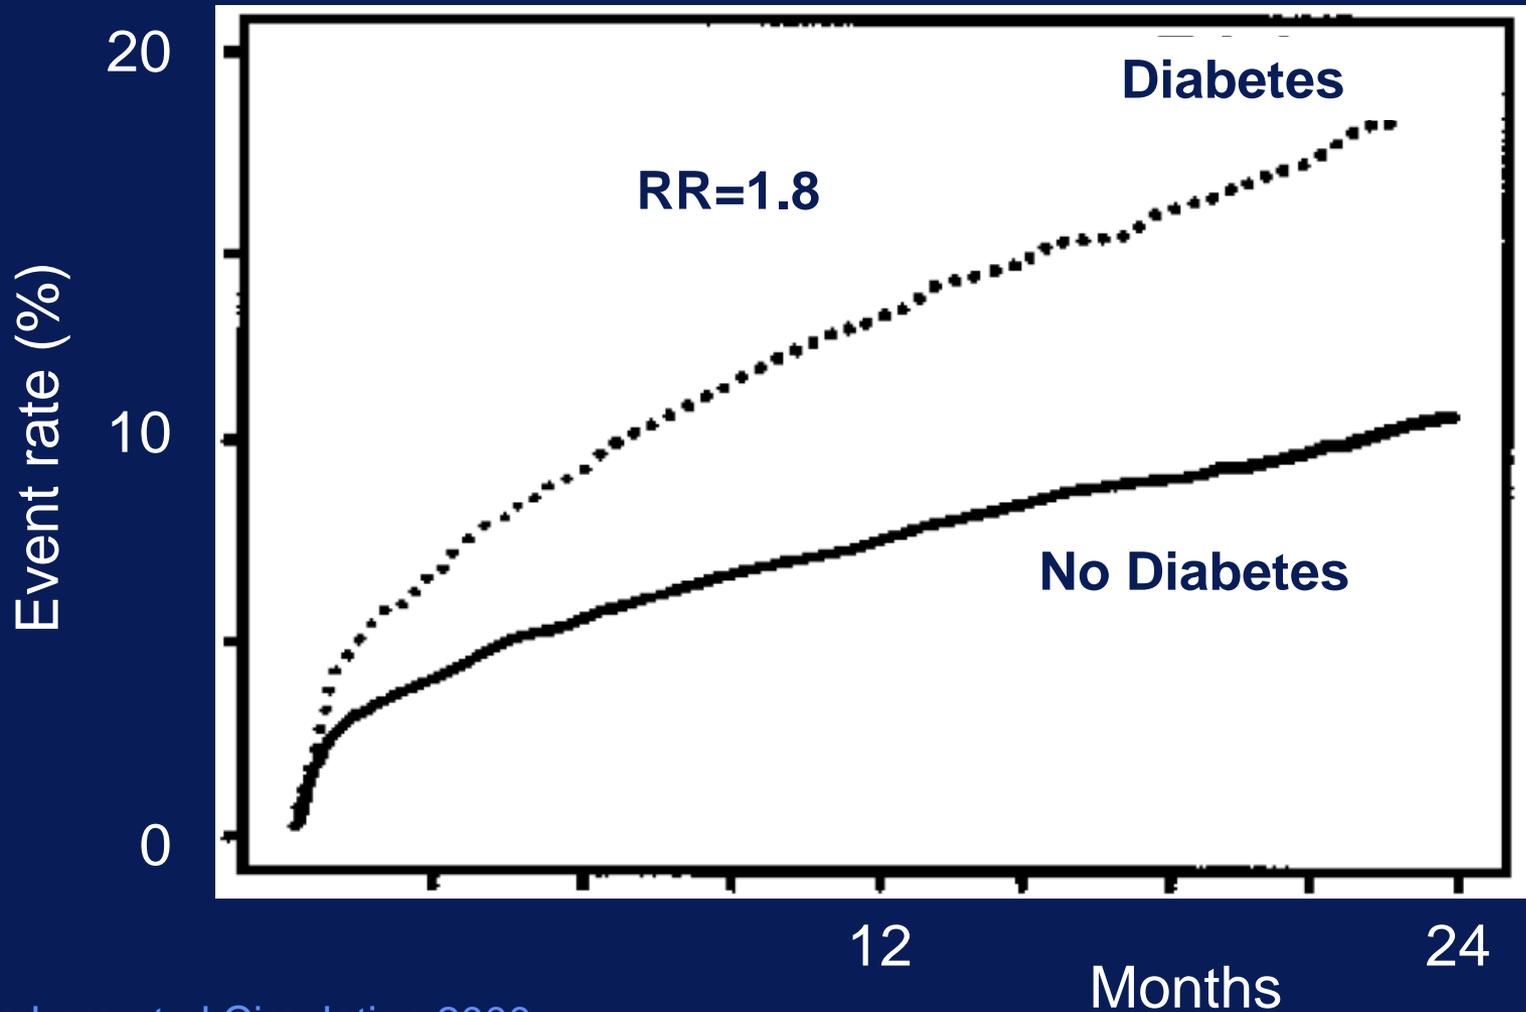

# Effect of diabetes over first year post MI

RIKS-HIA 1995-1998

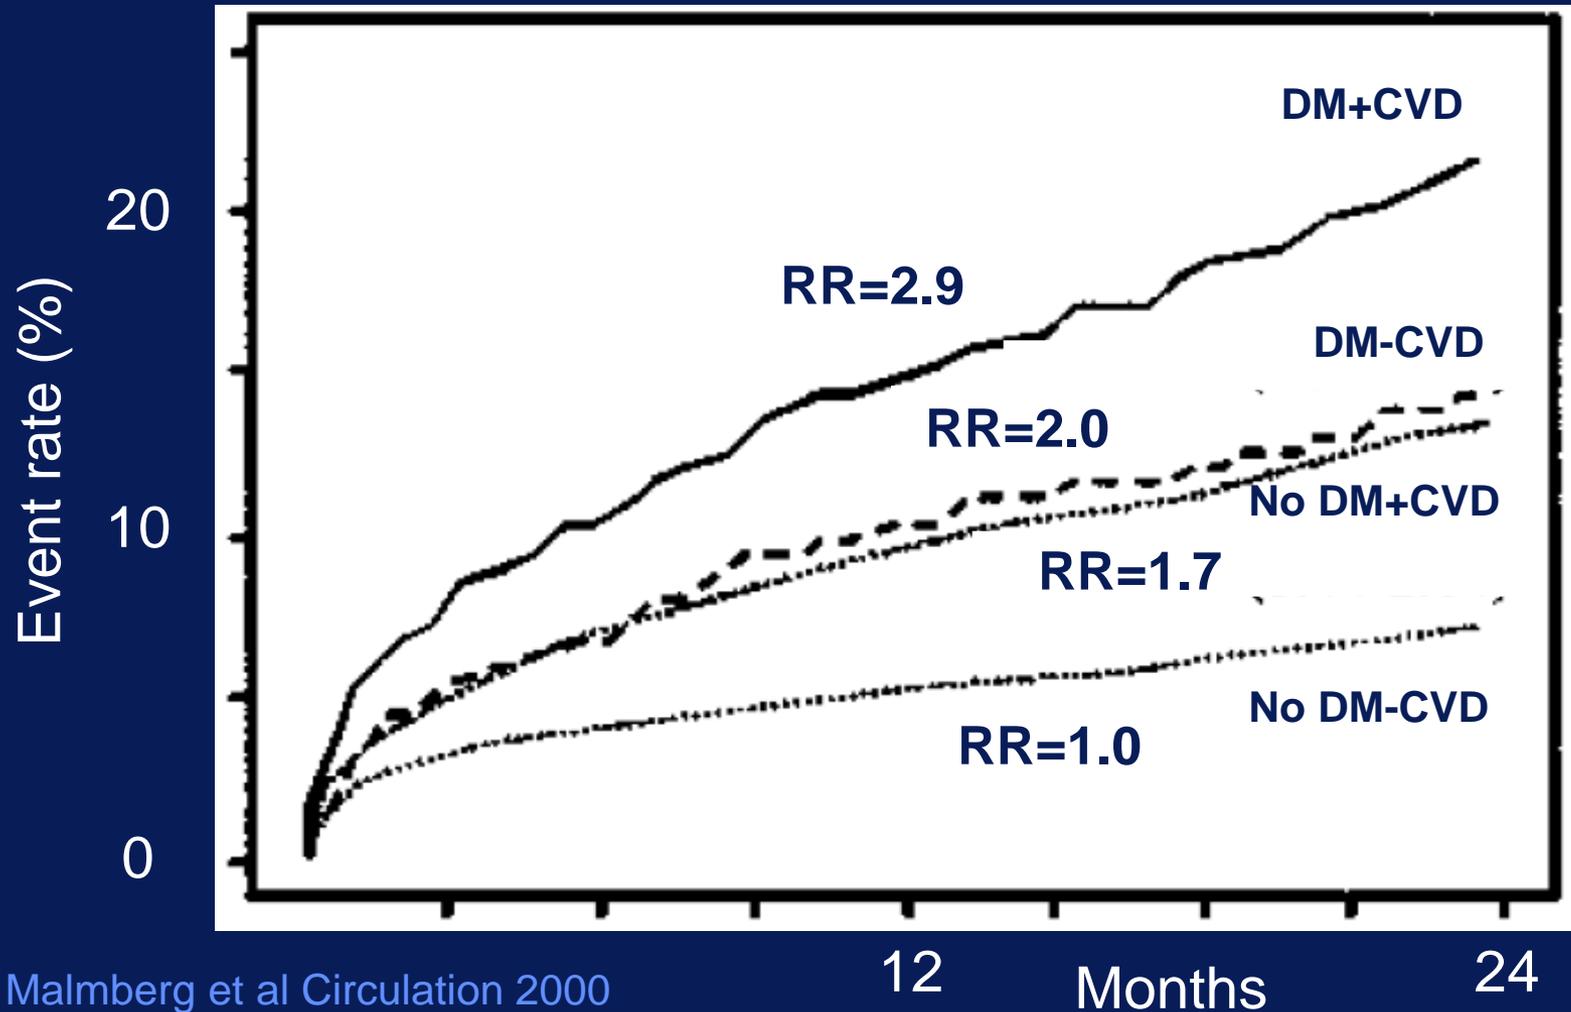

# Total mortality after ACS

(unstable angina and non-Q-wave MI)  
OASIS registry (21% of 8000 with diabetes)

# Total mortality after ACS according to history of CVD

# Carrying the motion demands positive responses to the following key questions

- Can the high risk of CVD
  - be usefully reduced by tighter glycaemic control?
  - be more successfully reduced by insulin compared to other agents?
- Are the benefits outweighed by the side effects?

# Outline

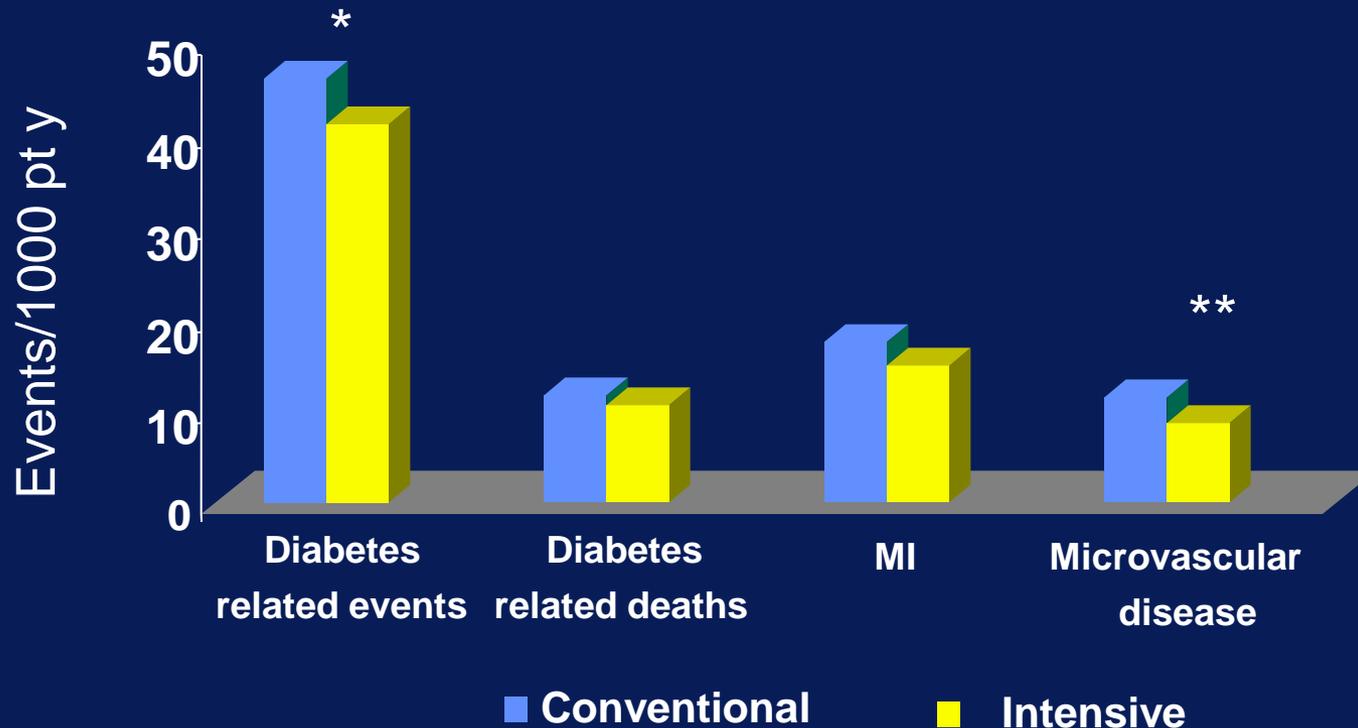

- Insulin treatment in Type 2 diabetes
  - Evidence of benefit
  - Evidence for harm
  - Side effects
  - What do the DIGAMI trials tell us?
- Conclusions

# UKPDS

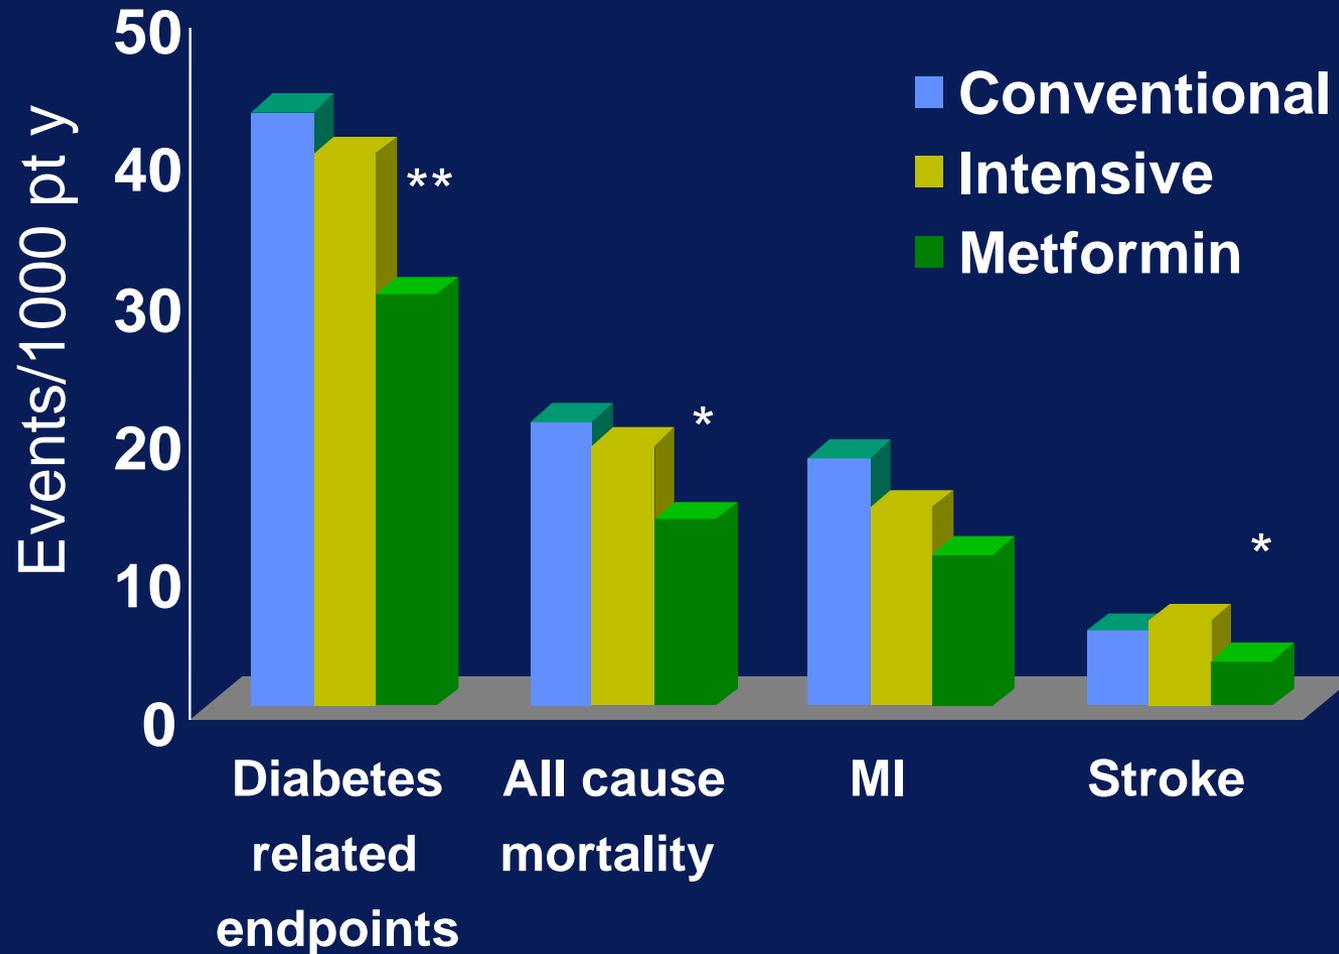

25% reduction in microvascular disease (mostly photocoagulation)

Complication -free interval for any diabetes event 14 vs 12.7y

Number needed to treat to prevent 1 event over 10y, 19.6 patients

# Effects of metformin in the overweight group

# Evidence for adverse effects of insulin on CVD (1)

## Endogenous insulin in humans

- Raised endogenous insulin levels an independent predictor of CVD
  - Paris Prospective Study (Fontbonne et al, Int J Obes 1988)
  - Helsinki Policeman's Study (Pyorala et al Diabetes Care 2000)
  - Buselton Study (Welborn et al Diabetes Care 1979)
    - Meta-analysis showed significant albeit modest effect of insulin (Ruige et al, Circulation 1998)
- Patients with IGT (normal fasting glucose and raised insulin levels) have increased CV risk (Unwin et al, Diabet Med 2000)

# Evidence for adverse effects of insulin on CVD (2)

## Exogenous insulin

- Increased ET1 (Hattori et al, Metabolism, 1991)
- Increased PAI-1 (Hsueh et al, Am J Cardiol 1999)
- Insulin treated
  - rats (Stout et al, BMJ 1970)
  - chickens (Stout et al, Atherosclerosis 1973)

have increased burden of atherosclerotic plaque

# Evidence for adverse effects of insulin on CVD (3)

Exogenous insulin observational studies

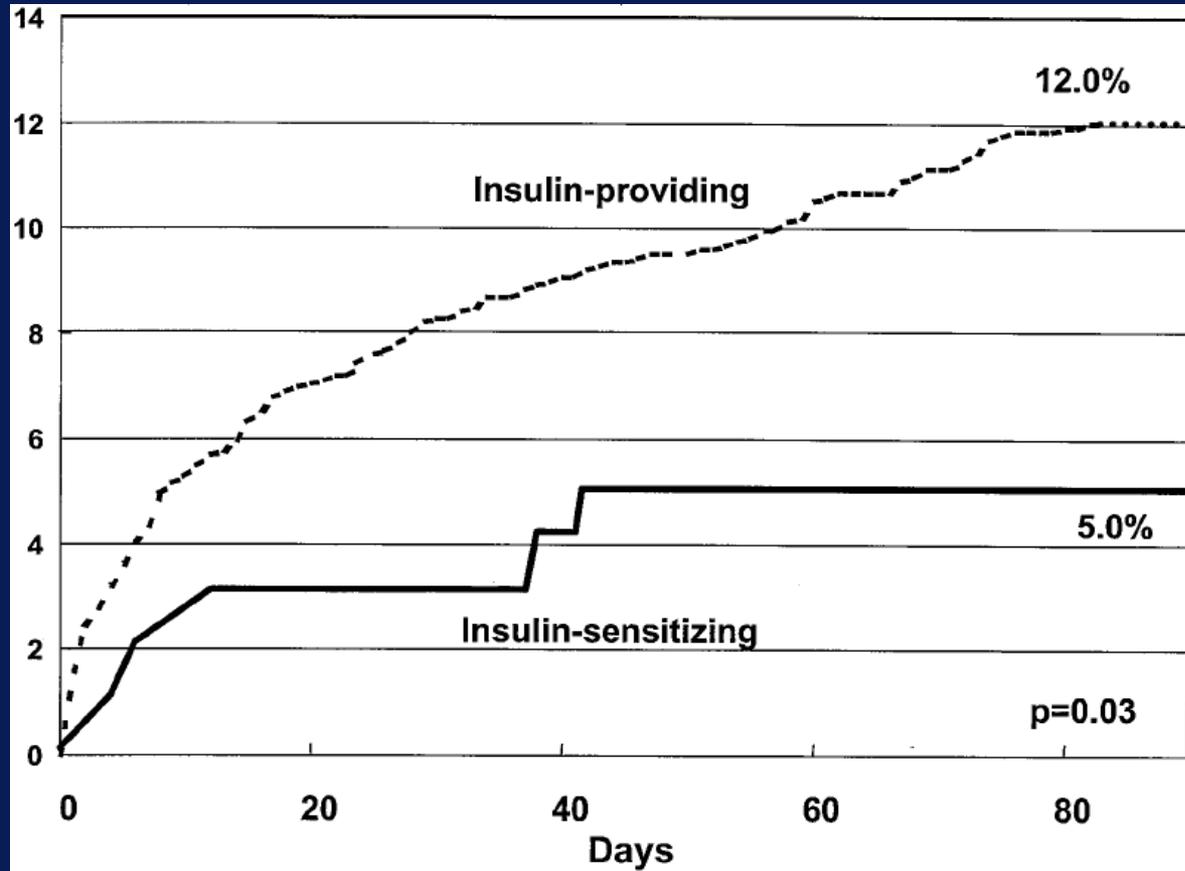

- Observational studies show adverse effects of insulin
  - Nelson et al, Circulation 1990
  - Janka et al, Diabetes Metab 1987

but subject to considerable confounding

- Meta-analysis of 6 studies involving exogenous insulin showed reduction in extent of cardiovascular disease but no effect on progression or mortality (Muis et al, Diabet Med 2005)

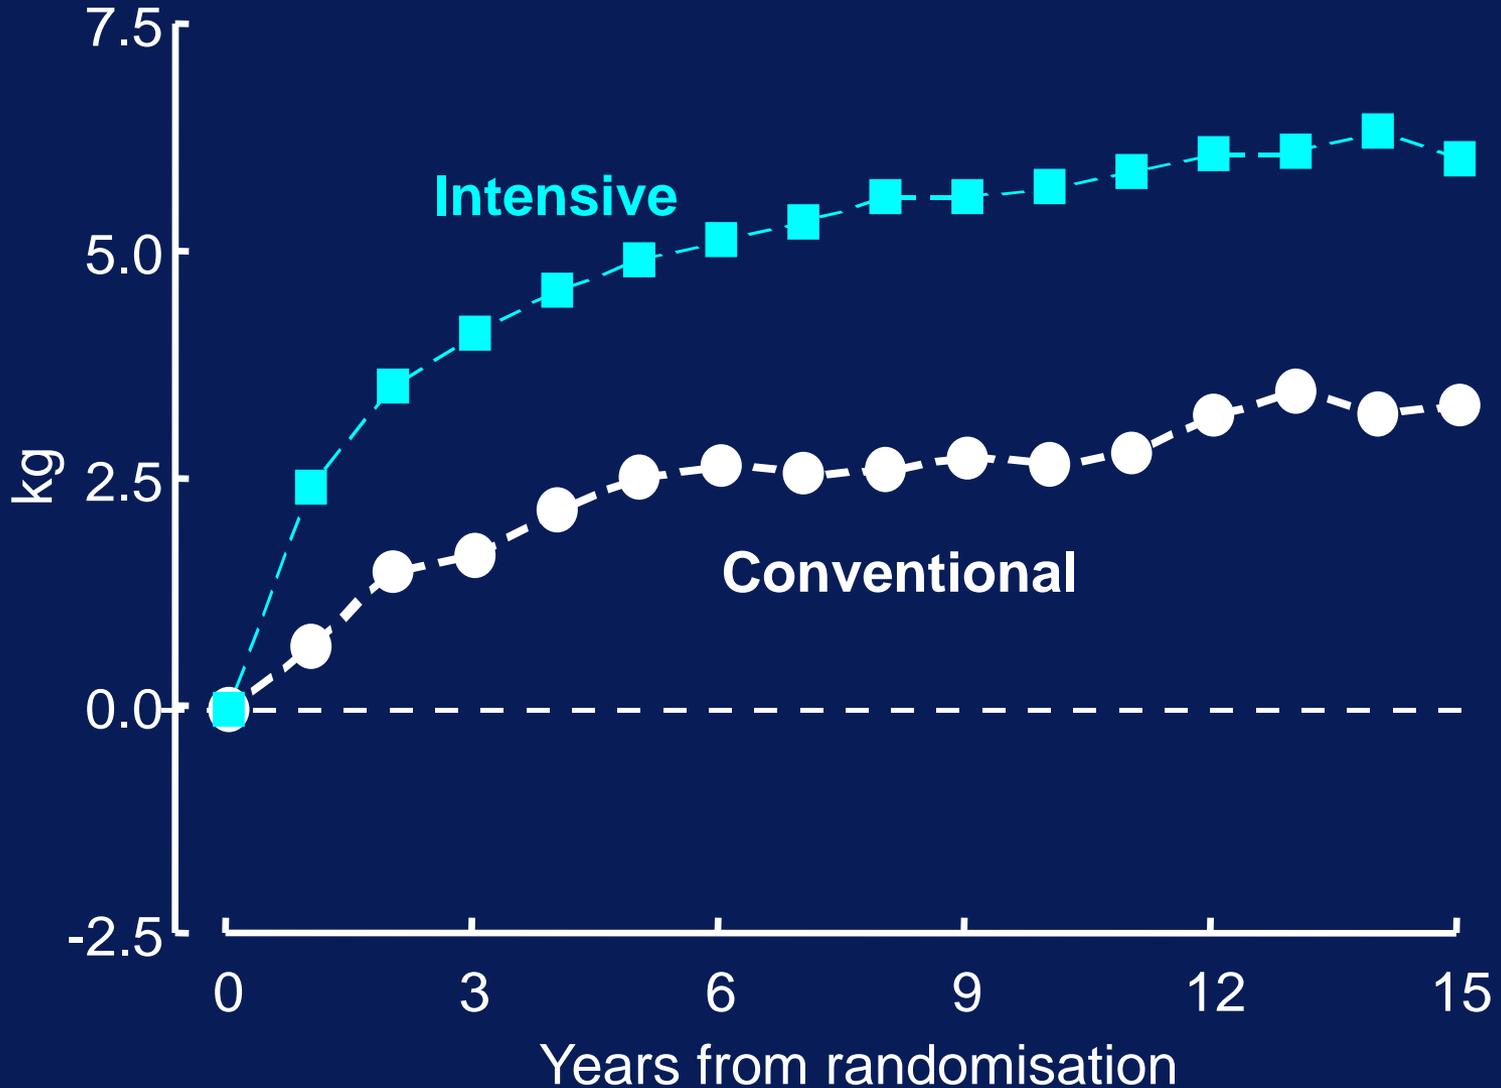

# Does blood glucose lowering therapy influence outcome in ACS?

Cumulative frequency (%)  
of death, MI, recurrent ischaemia

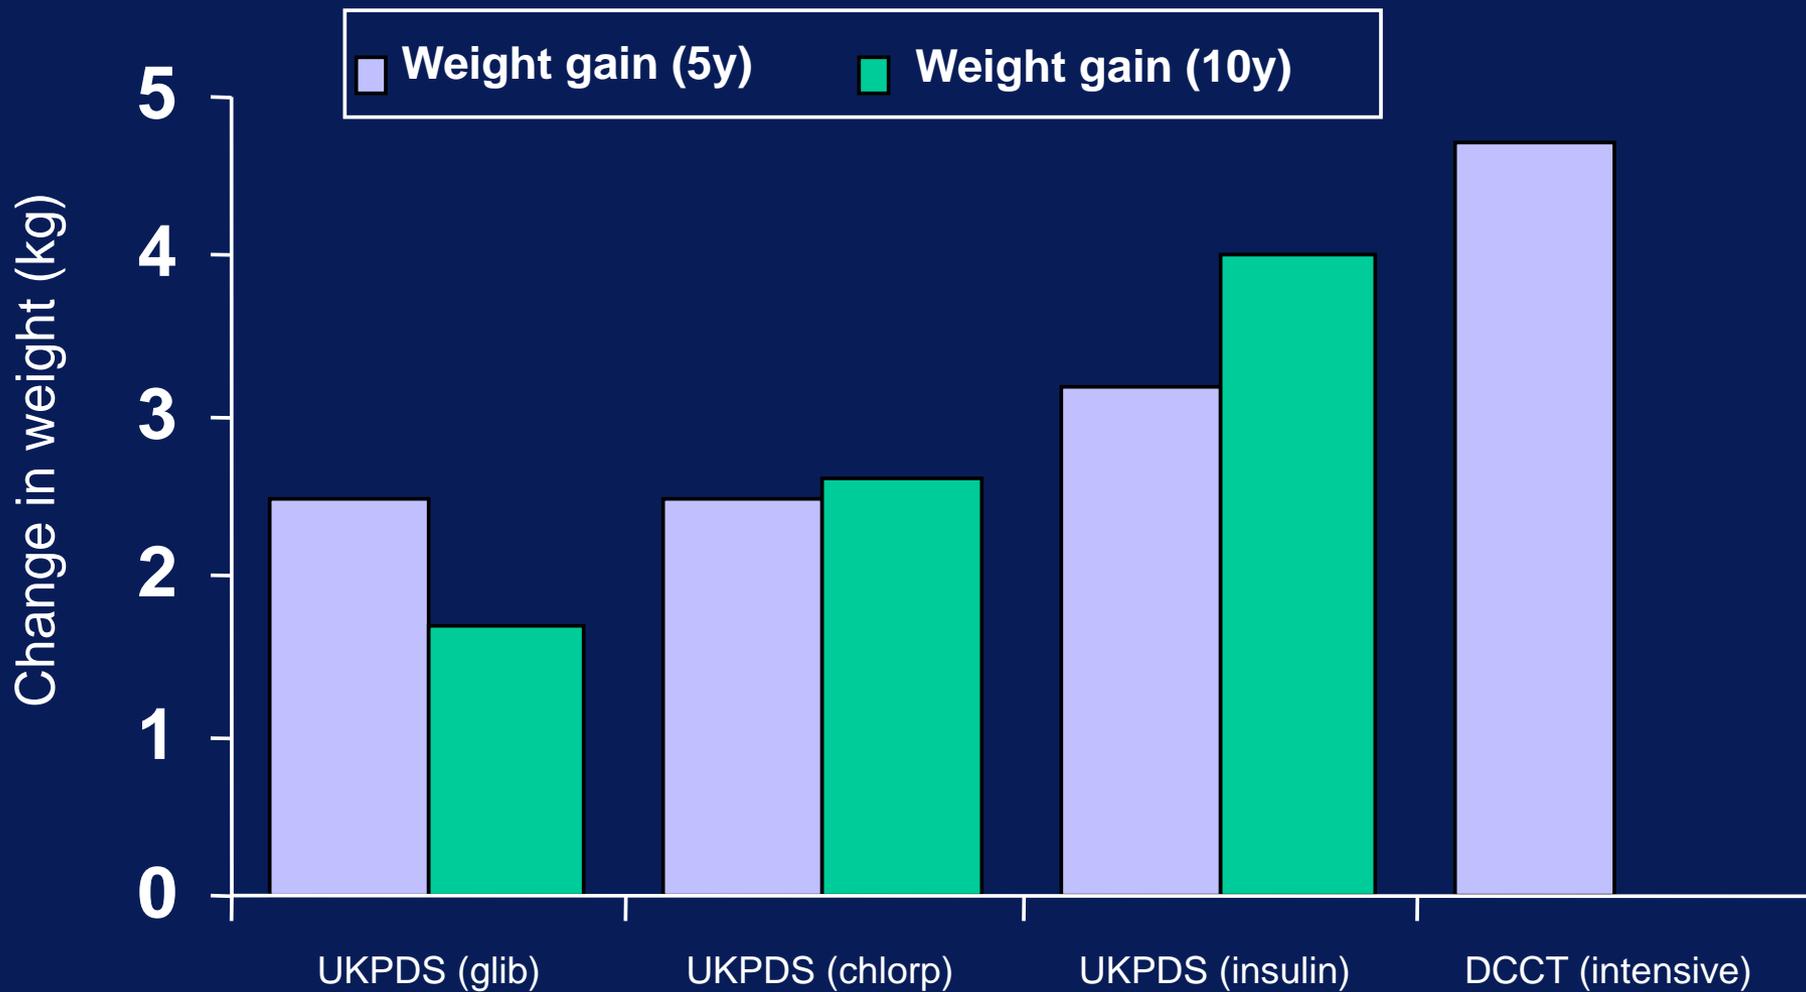

# Change in Body Weight

cross-sectional, mean values

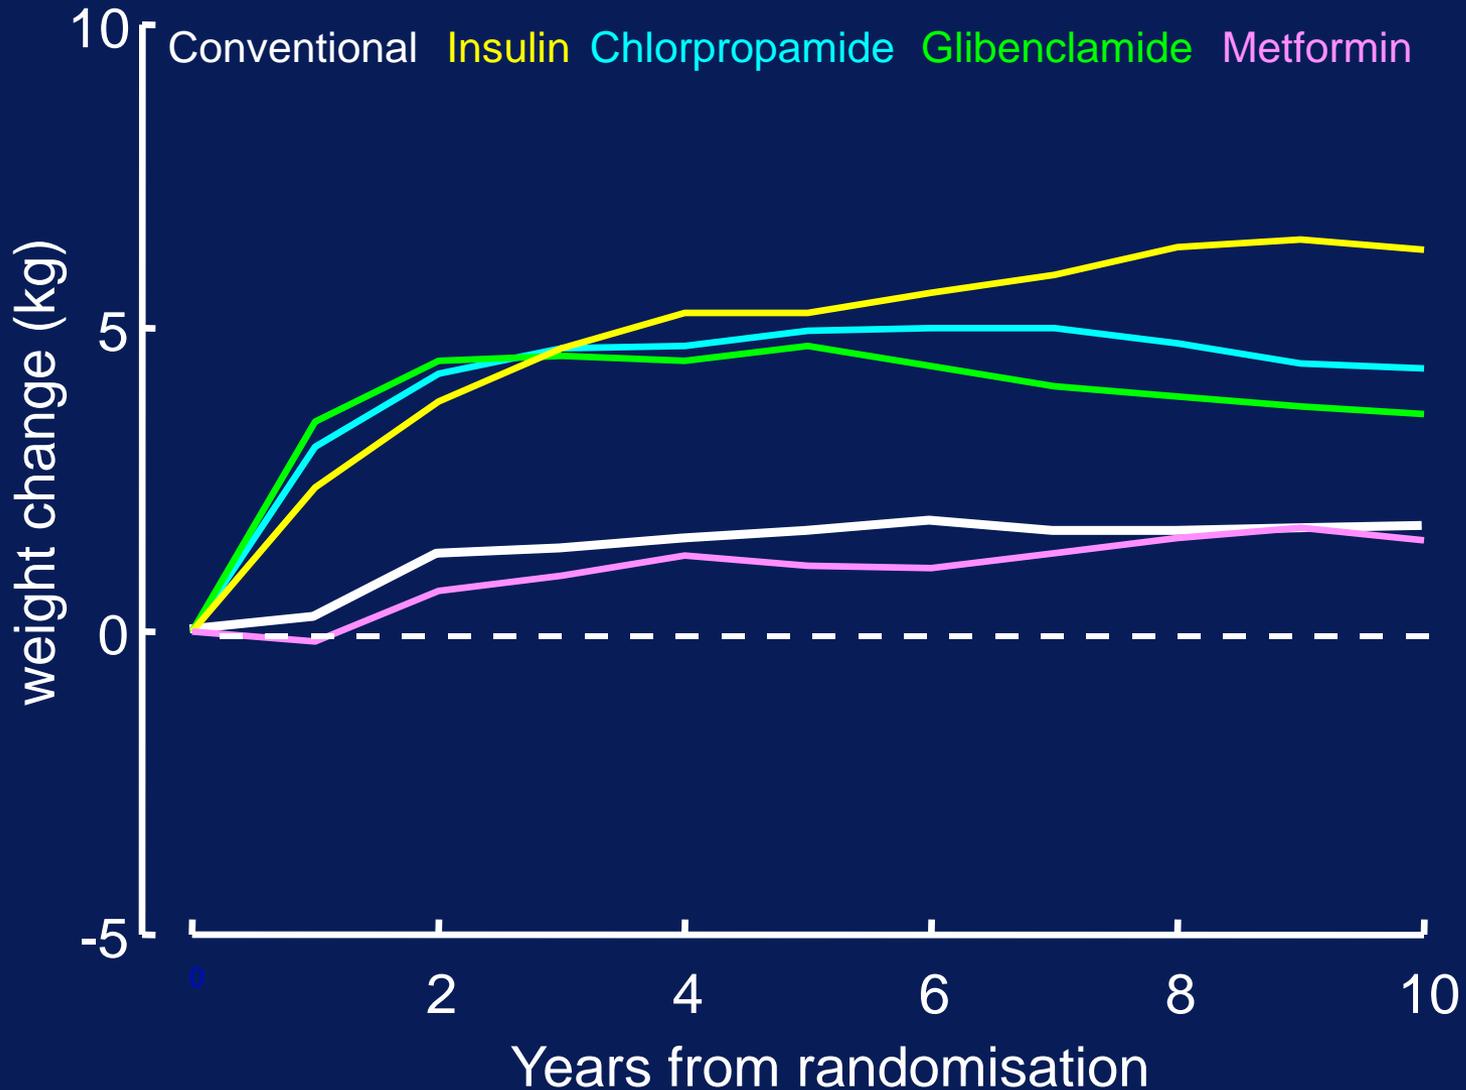

# Effect of treatment on weight gain

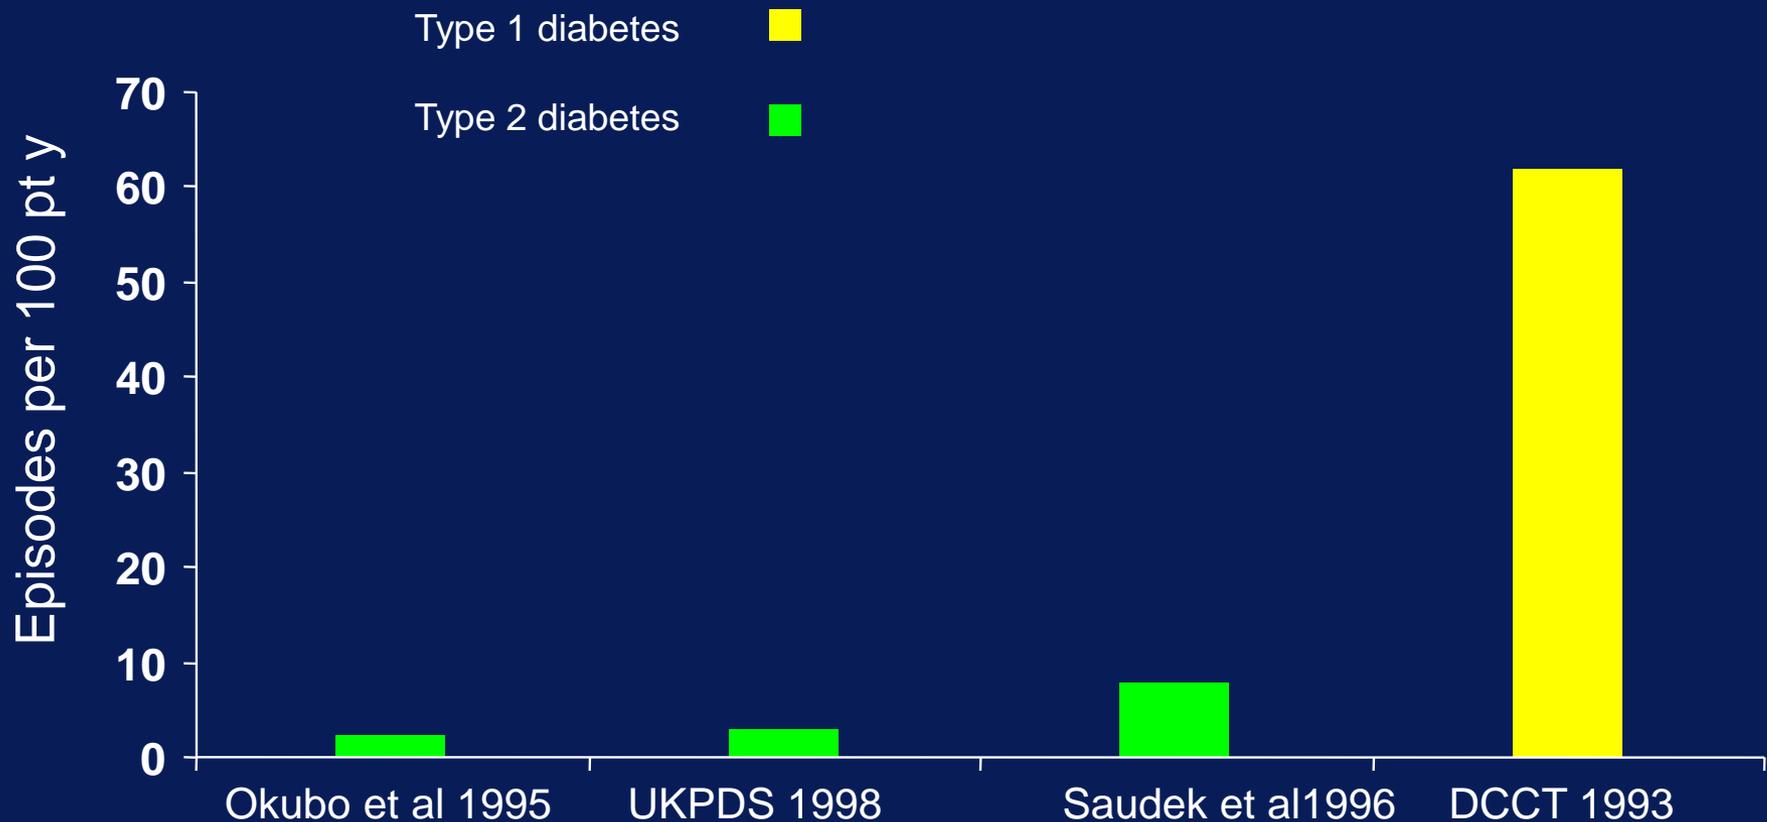

# Change in Weight

overweight patients

cohort, mean values

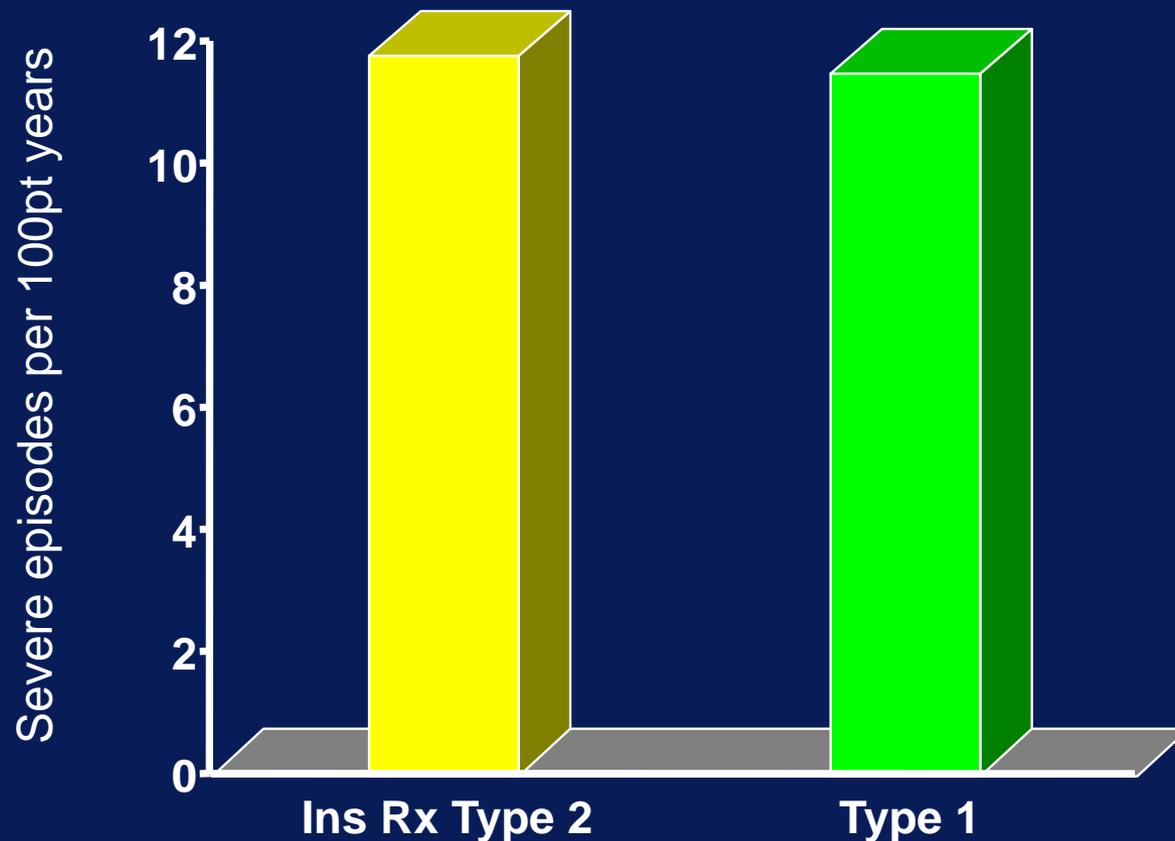

# Risks of hypoglycaemia during intensive insulin therapy

# Annual incidence of severe hypoglycaemia in a population based survey in Dundee

244 episodes in 160 patients, 69 Type 1 diabetes, 66 Type 2 diabetes on insulin  
23 in Type 2 diabetes on sulphonylureas

# Rationale for insulin in acute coronary syndrome in individuals with diabetes

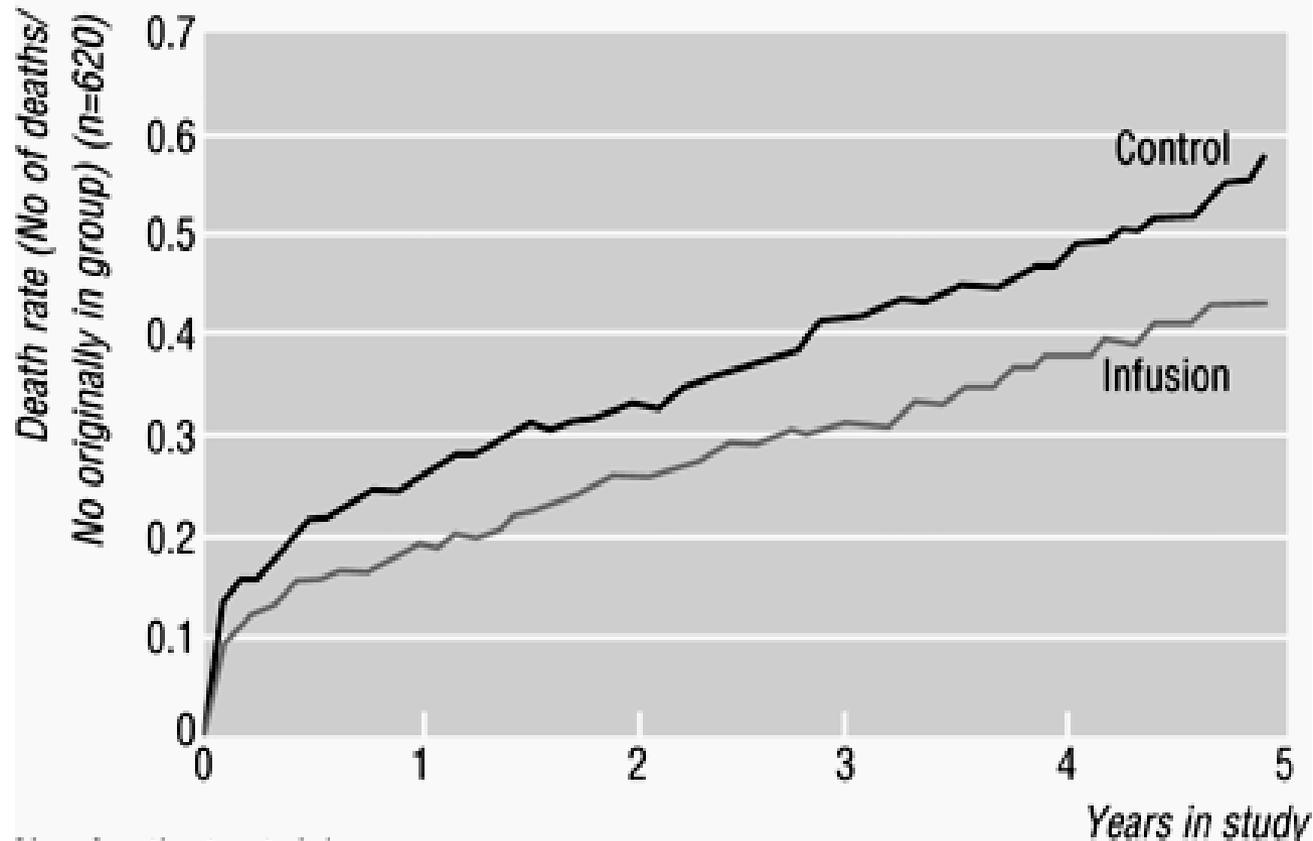

- Excess lipolysis and higher NEFA due to:
  - insulin resistance reducing glucose uptake
  - raised catecholamines
- Free radical generation, arrhythmias, reduced contractility
- Insulin/glucose infusions suppress NEFA

*Scientific rationale relates to the use of insulin infusion acutely*

# DIGAMI

24h of high dose insulin/glucose (no K) + 3m “intensive insulin”

Absolute risk reduction 11%, Relative risk 28%, P=0.01

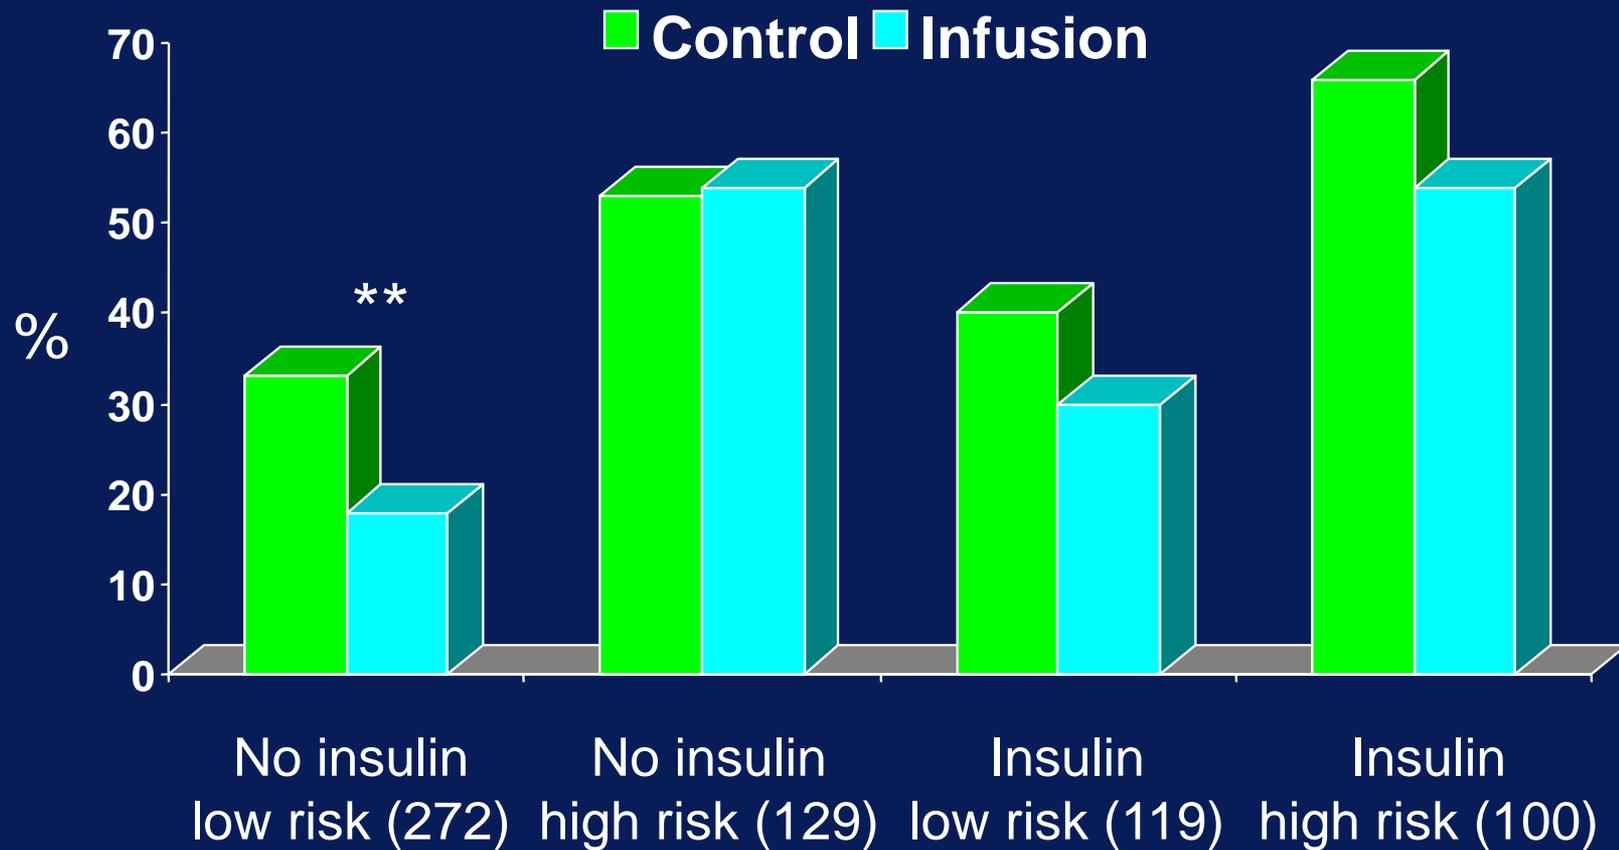

No of patients at risk

Control	314	232	187	116	58	14
Infusion	306	248	202	128	50	13

# DIGAMI 1

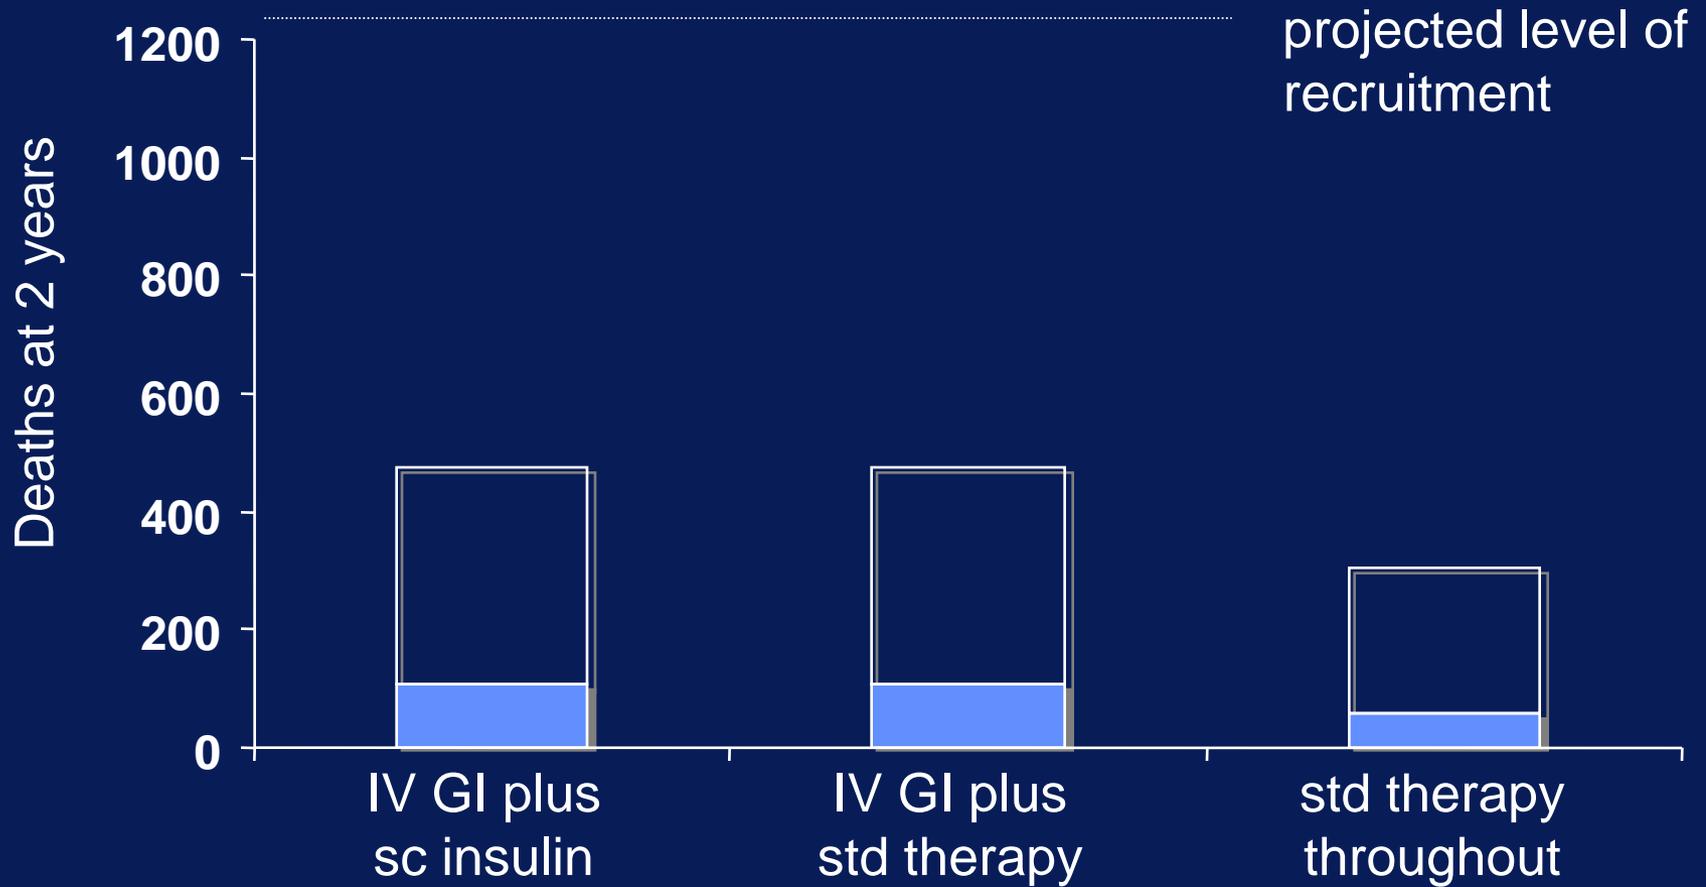

Long term mortality according to insulin and CV risk

# Outstanding issues following DIGAMI 1

- Do insulin/glucose infusions benefit those with IGT/without diabetes post MI?
- Do insulin/glucose infusions benefit those with diabetes and non STEMI and unstable angina?
- Which component is important, acute IV infusion or 3 months intensive insulin therapy?

# DIGAMI 2

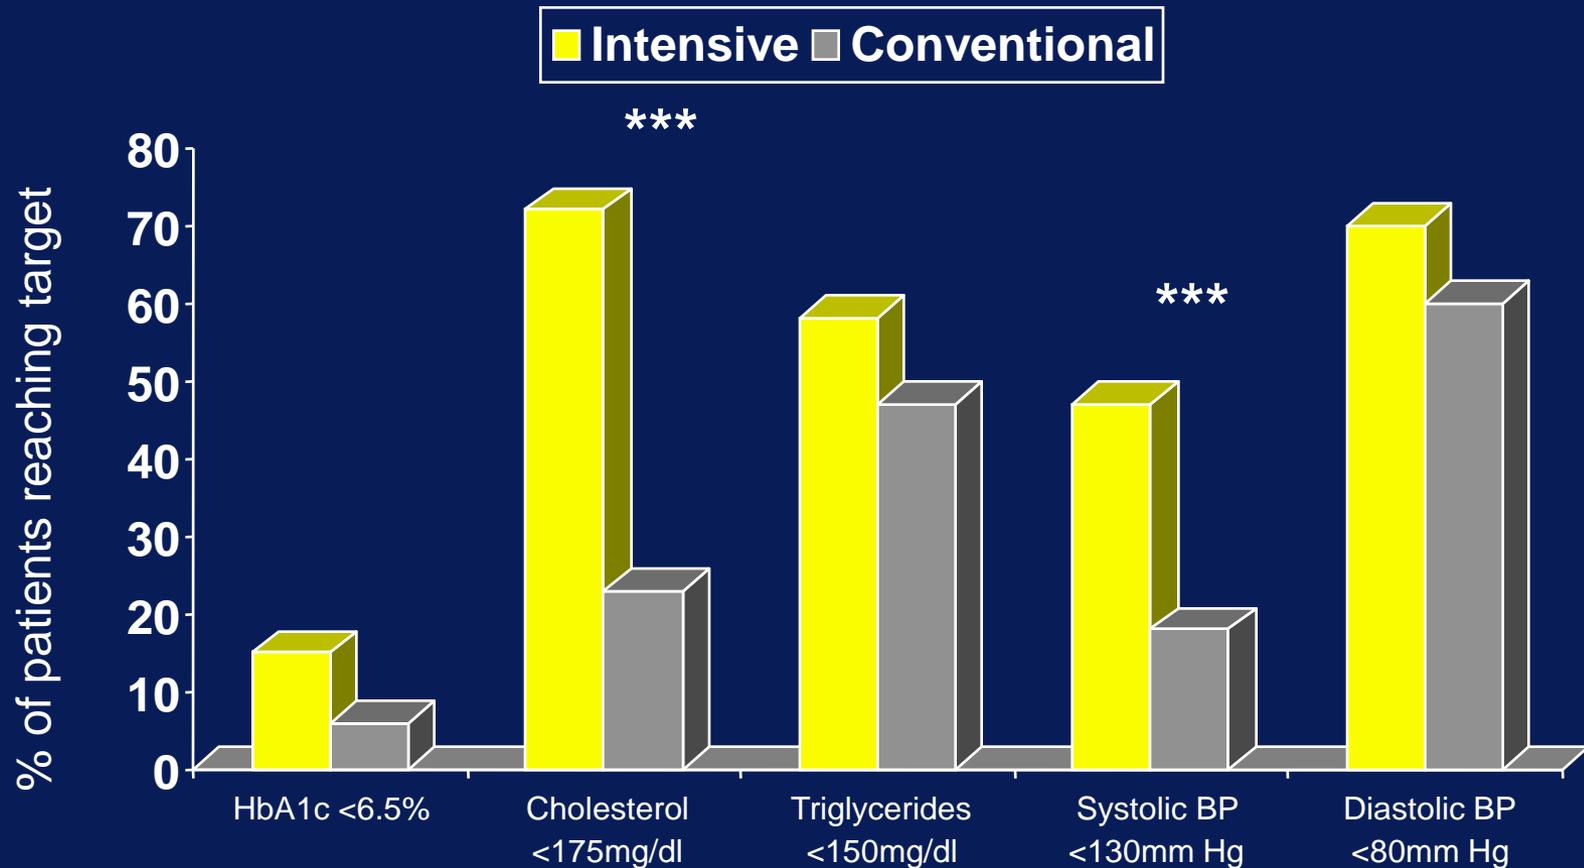

# Outstanding issues following DIGAMI 2

- Possible reasons for negative study
  - Underpowered
  - ‘contamination’ of controls
  - Lower glucose at admission
  - Low event rate due to secondary prevention therapy
  - Less aggressive sc insulin treatment
- Reasonable to use acute IV insulin infusion without proceeding to insulin therapy unless clinically indicated

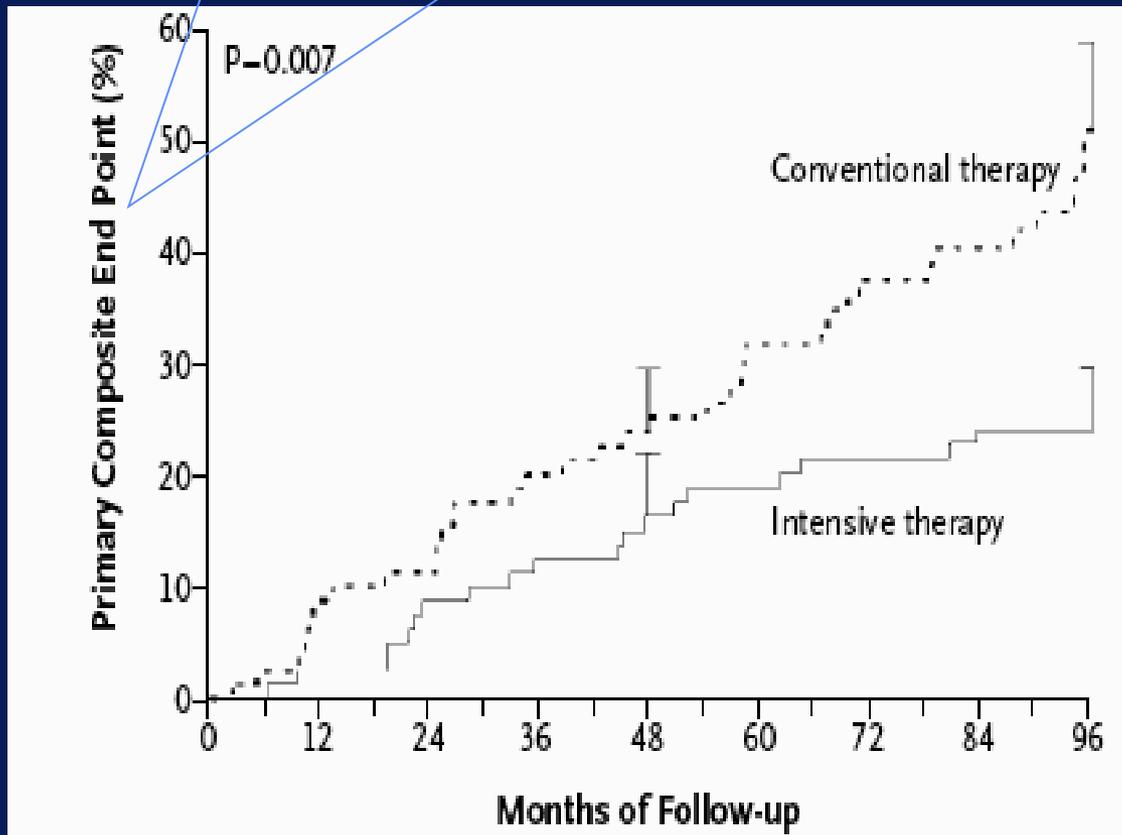

# Success of treatment in Steno -2 study

160 subjects with Type 2 diabetes and microalbuminuria randomised to intensive or conventional intervention

# Effect of multifactorial intervention in Type 2 diabetes

CV death, MI, stroke, amputation, revascularisation

85 events in 35 patients in std group (44%)

33 events in 19 patients in intensive group (24%)

20% absolute risk reduction  
equivalent to NNT of 5

?essentially related to tight control of lipids and BP

# Conclusions

- Little evidence that long-term tight glucose control involving insulin reduces CVD
- Effective lowering of lipids/BP may limit cardiovascular benefit of tight glucose control
- Side effects of hypoglycaemia and weight gain from aggressive glucose control will be unacceptable to many

*The case for early insulin treatment in those with CVD has still to be made*
